Stock market forecasting and trading is a challenging task for deep neural networks as it depends on many different variables, many of which are tied to dynamic real-world data. In this project, we aim to develop a language model agent as a trader recommender system. To achieve this, we will explore a variety of approaches, including fine-tuning pre-trained language models and using real-world news data to refine decision-making processes. If possible, we will experiment with explainable recommender systems which will make the developed trading system a rational, evidence-driven trading agent. The goal of this project is to employ a complete system with an agent interface that can interact with users, provide trading recommendations, and justify its decisions based on the state of the market.
